ABSTRACT

This experiment was conducted to evaluate the effect of feeding sweet potato vines on the digestibility in seventy-two weaned rabbits comprising males and females between six and weeks old, with initial liveweight ranging from 600 1130 g. They were allocated to twelve treatment diets in a 3 x 2 x 2 factorial experiment in a completely randomized design. The factors were sweet potato vines (0, 15 and 30 %), methionine (0.07 and 0.1 kg supplemental levels) and lysine (0.12 and 0.15 kg supplemental levels). the study lasted ten days with three days adjustment to crates and seven days of fecal and urine collection. Dry matter, crude fibre, ether extract, ash, acid detergent fibre and neutral detergent fibre digestibility decreased significantly as level of sweet potato vine increased. Interaction between sweet potato vines and lysine showed significant difference in acid detergent fibre and neutral detergent fibre. High level of methionine and lysine supplementation resulted in higher nutrients digestibility. It was concluded that supplementation of higher levels of methionine and lysine (0.1 and 0.15 kg) respectively in the diets of rabbits improved nutrient digestibility.

Key words: sweet potato vines, nutrient digestibility, methionine, lysine, weaned rabbits

INTRODUCTION

The use of leaf meals could help in alleviating the competition between humans and animals for some conventional feedstuffs, such as soybean meal and maize (Al-Harthi et al., 2009).

Sweet potato (Ipomoea batatas) is a herbaceous creeper plant which resists draught, has short generation interval of about four months, and can therefore be planted twice a year; hence its availability throughout the year is not in doubt (Hong et al., 2003). The leaves of this plant have been used in the tropics as a cheap protein sources in ruminant feeds probably as a result of its high protein contents (An, 2004; Ekenyem and Madubiuke, 2006). For instance, reports from several authors (Ali et al., 1999; Ishida et al., 2000; Ekenyem and Madubiuke, 2006; Adewolu, 2008) indicated that the leaf has high protein content (26 to 35%) with high amino acid content in addition to its good mineral contents including vitamins A, B2, C and E.

Despite the good nutritive content of the leaf meal, it has been reported to contain some amount of antinutritive factors namely invertase and protease inhibitor (Tacon, 1993). Sweet potato vines are palatable to rabbits and have been found to be more palatable that Leucaena leucocephala and the foliage of other legume trees (Raharjo et al., 1985).

Earlier, Oyenuga (1968) on observing the rich nutrient qualities of sweet potato leaves and stem recommended their use as source of feed for livestock in the tropics as using concentrates alone for raising rabbits would not be cost
Influence of methionine and lysine supplementation effective. However, sweet potato leaves alone may not have a good balance of nutrients that can support the optimal performance of animals. The objective of this study was therefore to evaluate the effects of methionine and lysine supplementation on nutrient digestibility in weaned rabbits fed graded levels of sweet potato vines.

**MATERIALS AND METHODS**

**Study Area**
The study was carried out at Bayero University, Kano Animal Science Farm Research Unit. It is located at the new site of the University, about 5Km West of Kano City in Ungogo Local Government Area of Kano State. Kano is located within the general area demarcated by the lines of longitude 8°E and 9°E and latitude 12°N and 13°N in the Northern Guinea Savannah Zone of Nigeria. The area has two seasons, the wet (May-September) and dry seasons (October-April). The annual temperature and rainfall ranges between 21°C and 39°C and 787mm to 960mm respectively (KNARDA, 2001).

**Experimental Design**
A 3 x 2 x 2 factorial arrangement in a Completely Randomized Design was used for this study. The factors were sweet potato vine at 0, 15 and 30% level, methionine at low (0.07kg) and high (0.10kg) levels, and lysine at low (0.12kg) and high (0.15kg) levels. The treatments were allocated to the experimental units completely at random. The model used is as shown below:

\[ y_{ijkl} = \mu + \alpha_i + \beta_j + \gamma_k + (\alpha\beta)_{ij} + (\alpha\gamma)_{ik} + (\beta\gamma)_{jk} + (\alpha\beta\gamma)_{ijk} + e_{ijkl}. \]

Where:
- \( y_{ijkl} \) = observation of factor 1 level i, factor 2 level j, and factor 3 level k for the lth unit
- \( \mu \) = population mean of y
- \( \alpha_i \) = effect of factor 1 (sweet potato vine level)
- \( \beta_j \) = effect of factor 2 (methionine level)
- \( \gamma_k \) = effect of factor 3 (lysine level)
- \( (\alpha\beta)_{ij} \) = interaction of factor 1 and factor 2
- \( (\alpha\gamma)_{ik} \) = interaction of factor 1 and factor 3
- \( (\beta\gamma)_{jk} \) = interaction of factor 2 and factor 3
- \( (\alpha\beta\gamma)_{ijk} \) = interaction of factor 1, factor 2, and factor 3
- \( e_{ijkl} \) = random variation of the observation

**Experimental Animals and their Management**
A total of 72 weaned rabbits used in this study were obtained from a local farmer. The rabbits were mainly of heterogeneous population, between six to seven weeks old with initial live weight ranging from 600g to 1130g. Six rabbits were allocated to each treatment, with three replicates of two rabbits per treatment. The study was conducted for 70 days (ten weeks). The animals were dewormed with Wormazine Hydrosoluble Antihelmintic at a dosage of 1g/litre of drinking water, Keproceryl WSP (Hydro soluble mix of antibiotics and vitamins) at a dosage of 0.5g/litre of drinking water was administered for 5 days and Anupco Vitalyte at dosage of 10g to 20 litres of drinking water as an anti-stress factor. Sweet potato foliage with the proximate composition shown in Table 1 was sun-dried and milled to obtain the sweet potato vine meal which was used in diet formulation.

The rabbits were weighed before the feeding trial and the treatment diets (Table 2) were gradually given to the rabbits to replace the feed they were used to for a week in order to allow the rabbits adjust to the experimental diets. The rabbit house and cages were thoroughly cleaned and disinfected before placing the rabbits in the cages with dimensions of 0.5m x 0.5m x 0.5m (0.125m3). The house and cages were cleaned daily. Aluminum feeders with dimensions of 0.25m x 0.10m x 0.8m were used as feed troughs for feeding the rabbits. The feeding was done at 08.00hours of the morning. Clean water was supplied to the rabbits ad libitum in aluminum drinkers with dimensions of 0.20m x 0.10m x 0.8m. Feed refusal was collected in the morning, weighed and used to determine feed intake. The feeders and drinkers were washed with clean water daily before new feed and water were offered.

Digestibility Study
The digestibility study was conducted at the end of ninth week of the feeding trial. Six rabbits were used per treatment in three replicates. The total amounts of feed given to two rabbits per replicate were recorded. The leftover and spilled feed were collected and weighed daily in the morning to calculate the feed intake. Faeces voided were collected from the particle-board floor of each cage cell of each replicate for seven days, sun-dried, weighed, recorded daily, stored in a cool and dry place in well labeled polyethylene bags, and used to determine digestibility criteria such as dry matter intake, and nutrient digestibility. Feed intake was determined daily for each replicate by weighing amounts of feed offered and leftover/spilled. The intake was expressed as the difference between the amount offered and the amount leftover/spilled.

Chemical Analysis
The sweet potato vines, diets, faecal droppings and rabbit carcass samples were analysed for chemical composition. The dry matter (DM), crude fibre (CF), ash, ether extracts (EE) and nitrogen free extract (NFE) were determined by method of AOAC (1990). The DM was determined by oven drying at 100°C to constant weight, fat by Soxhlet fat extraction method, Nitrogen–free extract (NFE) was calculated by the use of the following formula:

\[ \% \text{NFE} = 100 - (\% \text{CP} + \% \text{CF} + \% \text{EE} + \% \text{Ash}) \]

The acid detergent fibre (ADF), neutral detergent fibre (NDF) and hemicellulose were determined by the method of Van Soest et al. (1991). Hemicellulose was determined by the difference between NDF and ADF: NDF – ADF = Hemicellulose.

The nitrogen content was determined by the method of Kjeldahl (AOAC, 1990). Crude protein (CP) was calculated by multiplying the nitrogen content by 6.25.

Statistical Analysis
All data collected were subjected to analysis of variance using the General Linear Model Procedure (PROC GLM), for factorial experiment in a complete randomized design packaged in SAS (1987). When analysis of variance indicated significance for treatment effects, specific differences between means were detected and separated by Pair-wise Difference (pdiff) and Duncan's Multiple Range as described by Steel and Torrie (1980) and Duncan (1955).

RESULTS
Table 3 presents the effect of sweet potato vine level on nutrient digestibility of rabbits. Nutrient digestibility of dry matter, crude fibre, ether extract, ash, acid detergent fibre and neutral detergent fibre decreased as level of sweet potato vine increased. Dry matter, crude protein, crude fibre, ether extract, acid detergent fibre and neutral detergent fibre digestibility were higher in rabbits on 0% sweet potato vine than 15 and 30% sweet potato vine which were similar. Hemicellulose digestibility was higher in rabbits on 15% sweet potato vine than those on 0 and 30% sweet potato vine which were similar.

The results of the effect of methionine supplementation on nutrients digestibility is presented in Table 4. The results obtained showed that there was significant (P > 0.05) effect of methionine supplementation on ash and neutral detergent fibre digestibility of rabbits. Rabbits on high methionine supplementation level had a higher ash and neutral detergent fibre digestibility than rabbits on low methionine supplementation. Lysine supplementation had non-significant (P > 0.05) effect on nutrients digestibility of rabbits.

There was no interaction between sweet potato vine level and methionine supplementation on dry matter, crude protein, crude fibre, ether extract, ash, nitrogen free extract, acid detergent fibre, neutral detergent and hemicellulose digestibility.

DISCUSSION

Dry matter, crude fibre, ether extract, ash, acid detergent fibre and neutral detergent fibre digestibility decreased significantly as level of sweet potato vine increased in accordance with Dominguez (1992) and Close (1993) who stated that the inclusion of sweet potato foliage lowered the digestibility of all nutrients due to the increased fibre content of the diets. In contrast, the digestibility of dry matter, crude protein and crude fibre increased as the level of inclusion of sweet potato vines in the diets increased (Abonyi et al., 2012). Dry matter and crude protein digestibility obtained in this study are higher than that reported by Bamikole and Ezenwa (1999) who obtained dry matter digestibility of 0.45-0.56 and crude protein digestibility of 0.50-0.64 for combinations of concentrate and grass (guinea grass) or concentrate and legume (verano stylo). High level of methionine and lysine supplementation resulted in higher nutrients digestibility. This could be because methionine and lysine are essential for nutrients digestibility. This agrees with Ukpabi et al. (2008) who stated that raw bambarra groundnut offal should be supplemented with lysine and methionine to improve broiler feed conversion ratio, protein efficiency ratio, digestibility coefficient of crude protein and reduce feed cost. Dry matter and nitrogen free extract digestibility obtained in this study was lower than the values reported by Ajayi et al. (2007) and Abonyi et al. (2012) respectively. However, crude protein, crude fibre, ether extract and ash digestibility obtained were higher than values reported by Ajayi et al. (2007). Acid detergent fibre, neutral detergent fibre and hemicellulose digestibility of rabbits obtained in this study were high as a result of high fibre content of the diet. The nutrients digestibility recorded in this study is comparable with values reported by Adegbola and Okonkwo (2002) and Taiwo et al. (2005). Significant decrease in nutrients digestibility of rabbits fed graded level of sweet potato vine supplemented with low methionine and lysine levels showed that as the graded level of sweet potato vine inclusion increases so also the nutrients digestibility decreases. From the result of this study it could be concluded that optimum nutrients digestibility is achieved on higher levels of supplementation of methionine and lysine of 0.1 and 0.15 kg respectively when rabbits are fed sweet potato vines.
Influence of methionine and lysine supplementation
